Introduction

The primary objective of this research was to determine the polychlorinated dibenzo-p-dioxins (PCDD), polychlorinated dibenzofurans (PCDF) and dioxin-like polychlorinated biphenyls (dl-PCB) concentrations in bream (Abramis brama) and roach (Rutilus rutilus) muscle tissues collected from the different sites along Sulejów Reservoir (Central Poland). Both fish species are common in European freshwaters and represent major fish resources for recreational and commercial fisheries in eutrophic lowland waters. The distribution of PCDDs/PCDFs and PCB congeners were compared between the samples and discussed with respect to fresh and dry matter content, lipid content and possible sources of contamination and life-trait strategies of the two species. To our knowledge, no data on levels of PCDD/PCDF and dl-PCB concentrations in this region are present in literature.

Study area and Sampling

Fig. 1. Samples collection sites on Sulejów Reservoir.

Methods

Fig. 2. Total concentration of PCDD, PCDF and dl-PCBs (A) and toxic equivalent quantities (WHO-TEQ) (B) compared with the total length (TL) of analyzed bream.

Fig. 3. Total concentration of PCDD, PCDF and dl-PCBs (A) and toxic equivalent quantities (WHO-TEQ) (B) compared with the total length (TL) of analyzed roach.

Discussion and Conclusions

- Total concentrations of PCDDs/PCDF and dl-PCBs ranged from 885.43 to 988.71 pg/g of d.w. for roach (Rutilus rutilus) and from 521.69 to 994.94 pg/g of d.w. for bream (Abramis brama) (Fig. 2a and 3a);
- Toxic equivalent quantities (WHO-TEQ) ranged from 1.58 pg of WHO-TEQ/g of d.w. in roach to 1.94 pg of WHO-TEQ/g of d.w. in bream. The WHO-TEQ values calculated to fresh fish weight varied between 0.23 – 0.28 pg of WHO-TEQ/g of f.w. for roach, and 0.17 – 0.27 pg of WHO-TEQ/g of f.w. for bream (Fig. 2b and 3b);
- Obtained values did not differ statistically and were several times lower than the WHO-TEQ limits stated by Commission Regulation (EC), no 1896/2006 of 3 February 2006;
- Both species are eurytopic, tolerant fish and generally compete for similar food resources which would explain similar levels of tissues contamination. Observed small differences in WHO-TEQ levels (average values: 0.22 and 0.24 for bream and roach respectively) could be related to small diet shifts or age of sampled fish. Roach mostly feeds on mollusks (Dreissena polymorpha) and soft submersed macrophytes (genus Elodea or Ceratophyllum) while bream feeds on insects larvae especially Chironomidae. Bream grows more rapidly than roach, which specimens (average TL - 22.7 cm) were 2-3 years longer exposed to the contamination than bream (average TL - 23.7 cm).
